

Mobile Reflection

a. What mobile milestone did you implement?

Describe the feature or capability you implemented in your mobile application.

The main features I implemented were local storage and navigating between screens. Local storage is currently working - it saves created quizzes.

Additionally, navigating between screens is working - there is navigation between the home screen and the multi-screen quiz creation form.

b. How does navigation work in your mobile application?

The navigation uses a combination of stack and nested. Three screens exist in the stack - list screen (home page that displays the list of created quizzes), wizard screen - (takes user to the create/edit sequence), and taker screen (lets the user take one of the pre-existing quizzes). However, there is a fourth screen called quiz builder screen that is nested within the wizard screen and is not part of the main stack.

c. Where does your most important application state live?

The most important state in my project is called quizzes - an array of quiz objects with at least an id, title, questions, and often a thumbnail, and results. It is stored in the app because it affects all three of the main screens. The list view uses quizzes to render the created quizzes and uses the handlers that update quizzes (create, edit, and delete). The taker screen uses quizzes indirectly to render the quiz being taken. The wizard screen also uses quizzes indirectly to know if a quiz is being created or edited.

d. What was the most difficult part of implementing the mobile version?

I think the hardest part was trying to maintain the functionality of all the elements while restructuring it for mobile. Especially because there are multiple ways to get to one screen so at times one route would work but not the other.
